Introduction

What is Castep?

 A general-purpose 'first principles' atomistic modelling program

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- Based on density functional theory
- Used on many HPC machines, including HECToR

Written in

- Fortran 95
- BLAS/LAPACK for linear algebra
- FFT libraries (where available)
- MPI for parallel communication

Portable and well optimised

Introduction

What is Castep?

- Compute the electronic density
- Determine the groundstate atomic configuration and cell
- Simulate molecular dynamics (path-integrals, variable cell)

(日) (日) (日) (日) (日) (日) (日)

- Calculate band-structures and density of states
- Compute various spectra (optical, IR, Raman, NMR, XANES...)
- plus linear response, population analysis, ELF, etc.

Introduction

What is Castep?

What can't it do?

Excited states

- Optical properties
- Excited state MD
- Excitons
- Catalytic reactions

Low-Loss EELS

Introduction

How Castep Works

DFT overview

Lots of interacting particles in a potential.

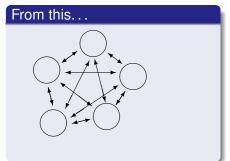

Independent (fictitious) particles in an effective potential.

Introduction

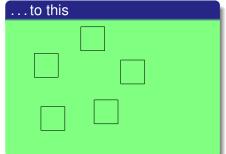

How Castep Works

DFT overview

Lots of interacting particles in a potential.

Independent (fictitious) particles in an effective potential.

Introduction

How Castep Works

Castep solves a set of Schrödinger equations,

$$\mathbf{H}_{k}[n]\psi_{bk}\left(\mathbf{r}\right)=\epsilon_{bk}\psi_{bk}\left(\mathbf{r}\right)$$

where *n* is the electronic density and $\{\psi_{bk}\}$ are the *bands*.

$$n(\mathbf{r}) = \sum_{bk} 2w_k \left| \psi_{bk} \left(\mathbf{r} \right) \right|^2$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Introduction

How Castep Works

Self-consistency

 $\mathbf{H}_{k}[n]\psi_{bk}\left(\mathbf{r}\right)=\epsilon_{bk}\psi_{bk}\left(\mathbf{r}\right)$

- H_k depends on $n(\mathbf{r})$
- *n*(**r**) depends on {ψ_{bk}}

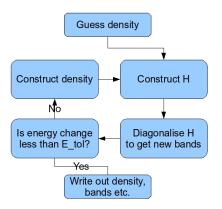

We need to solve this eigenvalue equation iteratively until we have *self-consistency*.

Introduction

How Castep Works

How Castep Works

≣▶ ≣ ∽۹..

Introduction

How Castep Works

A useful basis set

We expand ψ_{bk} in a plane-wave (Fourier) basis,

$$\psi_{bk}\left(\mathbf{r}
ight)=\sum_{G}c_{Gbk}e^{i\left(\mathbf{G}+\mathbf{k}
ight).\mathbf{r}}$$

The fundamental data object in CASTEP is the wavefunction data type, which stores the complex coefficients c_{Gbk} for all bands at all k-points: wvfn%coeffs(1:nG,1:nbands,1:nkpts) Thus for a given k-point, any band is just a vector of length N_G and the Hamiltonian \hat{H}_k is a $N_G \times N_G$ matrix.

Introduction

How Castep Works

A useful basis set

$$\psi_{bk}\left(\mathbf{r}
ight)=\sum_{G}c_{Gbk}e^{i\left(\mathbf{G}+\mathbf{k}
ight).\mathbf{r}}$$

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

If we increase the size of our simulation system:

- The size of the smallest G-vector decreases
- The number of **G**-vectors, N_G, increases
- On HPC machines N_G might be O(100,000)

Introduction

How Castep Works

The vectors $\{\mathbf{k}\}$ sample the region of reciprocal-space

$$|\mathbf{k}| < rac{1}{2} |\mathbf{G}_{\textit{smallest}}|$$
 .

We increase the \mathbf{k} -point density until our calculation converges. If we increase the size of our simulation system:

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

- The size of the smallest G-vector decreases
- The number of **k**-points we need *decreases*
- On HPC machines N_k might be O(1)

Time-Dependent Density Functional Theory

Perturbative approach

- Analogous to DFT
- Density is now dependent on time: $n(\mathbf{r}, t)$
- Can be solved with a perturbative approach
- Excitation energies ω are poles of:

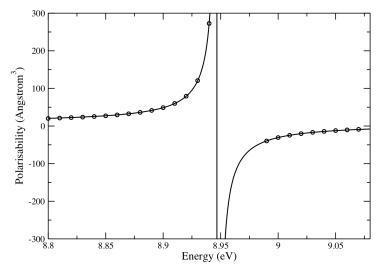

$$\sum_{i,j=1}^{N} \left(H\delta_{ij} - \epsilon_{ij} \right) \left| \Phi_{j}^{\{\pm\}} \right\rangle + P_{c} V^{\{\pm\}}(\pm \omega) \left| \Phi_{i}^{\{0\}} \right\rangle = \mp \omega \left| \Phi_{i}^{\{\pm\}} \right\rangle$$

Time-Dependent Density Functional Theory

Tamm-Dancoff Approximation

Eigenvalue problem

• Poles of the earlier equation can be found directly by solving a Hermitian eigenvalue problem.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

•
$$(\mathbf{A} + \mathbf{B}) \left| \Phi^{\{\pm\}} \right\rangle = \omega \left| \Phi^{\{\pm\}} \right\rangle$$

•
$$A \left| \Phi^{\{\pm\}} \right\rangle = (H - \epsilon) \left| \Phi^{\{\pm\}} \right\rangle$$

•
$$B \left| \Phi^{\{\pm\}} \right\rangle = P_c V^{\{1\}} [n^{\{1\}}] \left| \Phi^{\{0\}} \right\rangle$$

Time-Dependent Density Functional Theory

Tamm-Dancoff Approximation

Self-consitent

- B depends on $n^{\{1\}}$
- $n^{\{1\}}$ depends on $\left|\Phi^{\{\pm\}}\right\rangle$

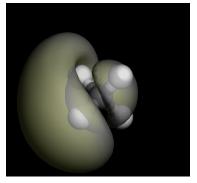

Need an iterative method to solve.

- Initially start with canned serial library.
- ARPACK Arnoldi method
- HSL EA19 Rayleigh quotients with conjugate gradients and preconditoning
- Both have reverse communication interface
